TITLE: Corrosion of special steels in naphthenic acids

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 12, 1961, 324, abstract  
12W180 (12I180) ("Azerb. neft. kh-vo", 1960, No 11, 43 - 45)

TEXT: A study of the corrosion rates of 15 different brands of stainless  
steels in naphthenic acids at 200 - 275°C showed that Cr steels have a high  
corrosion rate, Cr-Ni steels a low corrosion rate attaining high values at  
275°C, and that Cr-Ni-Si steel (Si: 3-6 %) has an exceptionally high stabil-  
ity. This is explained by the properties of the protective films formed in  
presence of Si. [Abstracter's note: Complete translation.] X

TITLE:

The Experience in the Operation of Small-Size Presses  
MGP-3 and MGP-12

PERIODICAL:

Energetik, 1959, Nr 7, pp 16-18

(USSR)

ABSTRACT:

The small-size hydraulic presses MGP-3 and MGP-12 are not used at some power distribution system because of minor design defects and lacking knowledge of the adjustment of the valve mechanism. The experience in operating these presses by the Mosenergo power distribution system resulted in uncovering and eliminating some minor design defects. The author cites the deficiencies which were observed when operating 100 presses of type MGP-3. Failures of the valve mechanism are caused by minute mechanical particles and the author suggests using a brass screen as a filter. In his conclusions the author emphasizes that the experience during many years proved the reliable operations of presses MGP-3 and MGP-12, provided proper adjustments are made. The author further gives

TITLE: The problem of investigating pilot work capacity during long sojourns in  
spaceship mockups [Paper presented at the Conference on Problems of Space Medicine  
held in Moscow from 24 to 27 May 1966]SOURCE: Konferentsiya po problemam kosmicheskoy meditsiny, 1966. Problemy  
kosmicheskoy meditsiny. (Problems of space medicine); materialy konferentsii,  
Moscow, 1966, 169-170TOPIC TAGS: isolation test, human physiology, hypodynamia, respiratory system,  
space physiologyABSTRACT: On prolonged spaceflights, cosmonaut work activity will take place  
during the exposure of the organism to a whole group of unusual factors  
(weightlessness, prolonged isolation, hypodynamia, altered gas medium,  
and so forth). Study of the effect on man of these factors is of great  
practical importance.

The purpose of the present investigation is to study the condition and  
work capacity of man during a prolonged sojourn in a spaceship mockup.

Card 1/3

ACC NR: AT6036561

was more pronounced. Thus, on the first, fifth, seventh, and eleventh days, a one and one-half to two-fold decrease in the accuracy of ship attitude control from angular coordinates was recorded. The time required for information transmission increased toward the end of the experiment by an average of 10%. In the correction tests, the information capacity of the visual analyzer dropped from 1.7 to 1.3—1.5 bits/sec. The red and blue light contrast sensitivity of the eyes decreased 35% and 40%, respectively, from L. N. Meyer's data.

Numerous changes in physiological indices were also noted toward the end of the experiment. Thus, for example, the EEG's showed a stagnant exaltation of alpha rhythms. Tests with sudden random signals requiring a response reaction from the subject showed a decrease in electromyogram amplitude from 300—200 $\mu$ v and a galvanic skin response amplitude decrease from 650—480 $\mu$ v.

The observed functional shifts in the state of the subject during a 12-day stay in a spaceship mockup indicate that further study of pilot work capacity under analogous conditions is necessary, as is an effort to find optimal work-rest schedules for cosmonauts on prolonged spaceflights. It was noted that the cosmonauts did not tolerate re-entry as well as they did centrifugation during training. This was attributed to the day-long exposure to weightlessness. None of the observed deviations

Card 6/7

TITLE: The tolerance of animals to shock overloads acting in the direction close to the long axis of the body

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Seriya biologicheskaya, no. 1, 1962, 90-95

TEXT: Freely fastened animals (dogs) were catapulted with an overload of 20-23 units, in supine, sitting, and standing positions, for 0.1-0.5 seconds. The animals were subjected to a negative overload (direction pelvis-head) in the final stage of the experiment. The soft tissues of the animals, as well as the supporting apparatus, were not affected by the experimental conditions. The catapulting brought about transient functional changes in the cardio-vascular and respiratory systems, which returned to normal within 4-5 minutes. The results obtained were useful during the planning and performing of the space flight in the second, fourth and fifth space ships—sputniks. There are 4 figures and 2 tables.

TITLE: Changes in certain morphological and biochemical indices of the peripheral blood of animals after rocket flights

SOURCE: Problemy kosmicheskoy biologii. v.1. Ed. by N.M. Sisakyan. Moscow, Izd-vo AN SSSR, 1962. 161-165

TEXT: Determinations of blood count and blood biochemistry were carried out on 12 dogs which had undergone 2 to 5 space flights. Blood samples were taken on the eve of flight, 1.5 to 2.5 hours after landing, and also at later stages; 42 investigations were carried out in all. After the flight an increase in white cell count by 1800 - 11050 cells per mm<sup>3</sup> was noted, due mainly to an increase in neutrophils with a shift to the left of up to 30% of unsegmented forms. These changes were ascribed to a redistribution of cells from depot organs under the influence of mechanical forces, although a stress reaction may also have been concerned. No changes were noted in the red cell count, but after space flight there was a reduction in clotting time, with

TITLE: On some responses of human subjects to sub-gravity  
conditions

SOURCE: Problemy kosmicheskoy biologii. v. 2. Ed. by N. Sis-  
kyan and V. Yazdovskiy. Moscow, Izd-vo AN SSSR, 1962,  
206-214

TEXT: This article was presented at the 10th European Con-  
gress on Aviation and Space Medicine, Paris, 26-30 September, 1961.  
The authors investigated the nature of sensory response and the de-  
gree of change of some motion indicators of human subjects under  
sub-gravity conditions. The experiments were conducted in a parabolic flight with weightlessness periods of up to 10 sec. The statistical  
analysis of the experimental material showed that all the subjects  
can be divided, from the point of view of their sensory responses,  
into 3 groups: a) those subjects whose general state did not change.

Card 1/3

(In some responses ...)

iorate or who even experienced a feeling of relief or comfort; b) those who were disoriented and could no longer properly respond to environment; however, after 12-15 trials of weightlessness they became fully adapted to it; c) those who temporarily lost their weight capacity; in these cases 20-30 periods of weightlessness were necessary for their adaptation. It is noted that the first two types of reactions are applicable to short periods of weightlessness. In the experiments, the muscular force of the hand was measured and the ability of making and sustaining a prolonged effort was analyzed. In 266 measurements on 26 subjects it was found that the muscular force of the hand decreased (in 82% of the cases) from 45-65 kg to 4-22 kg. A special dynamograph with visual control was used in the experiments. It was found that in the first seconds of weightlessness the muscular force underwent fluctuations ranging from 0 to 400 gm. It can be assumed that in operating the control levers, designed for a force of up to 400 gm, the accuracy of the muscular effort during the transient periods can vary considerably; this can prove a major factor in equipment control on board space ships. Conclusions: From the point of view of sensory response,

Card 2/3

In some responses ...

S/865/62/002/000 /020/042  
D405/J301

all human subjects can be divided into 5 groups. At the initial stage of weightlessness, various changes in motor-force indicators are observed. Weightlessness is accompanied by regular changes in the bioelectric activity of the neck muscles that manifests itself by a marked drop in biopotential amplitude (from 40 to 25 microvolt). Parabolic flights on aircraft can be used not only for weightlessness experiments, but also for space flight crew selection and training. The majority of selected subjects do not experience sensory ill-effects under weightlessness conditions. There are 4 figures.

TITLE: Motor activity of intact animals under conditions of artificial gravity

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Seriya Biologicheskaya, no. 3, 1962, 455-460

TEXT: The minimal effective value of artificial gravity necessary to maintain the body posture and coordination of movements of mice and rats under conditions of weightlessness as in the parabolic flight of an aeroplane was determined. Artificial gravity was created in a small size centrifuge which produced radial accelerations varying from 0.05 to 1.0 g. Accelerations of 0.28 to 0.3 g were sufficient for prophylaxis of the unfavourable effect of weightlessness upon the motor reactions of the animals. There are 2 figures and 1 table. TITLE: Some physiological responses of man under the conditions of alternating effect of overloads and short-term weightlessness

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Seriya biologicheskaya, no. 6, 1962, 896 - 907

TEXT: Investigations were carried out to study the behavior of 55 test persons in a number of flights on special aircraft, where short-term weightlessness (up to 45 sec) was reproduced in parabolic flights. It was found that changes in the basic indices of the function of the cardio-vascular and respiratory systems during an alternating effect of overloads and weightlessness were within the bearable limits of physiological variations; these changes were short-term and of a reversible nature. Thus during the action of overloads, accelerated breathing and an increased pulse rate could be observed in most cases, as well as some functional changes of cardiac activity. In the state of short-term weightlessness the indices of the cardio-vascular system revealed a trend to nor-

malization. Individual features of physiological responses of the persons tested to the alternating effect of increased and reduced gravitation could be observed. The test data obtained can be used as a basis for elaborating training measures relative to the effect of the factors mentioned. There are 5 figures and 4 tables.

TITLE: The reaction of cosmonauts to short-term weightlessness

SOURCE: Konferentsiya po aviatcionnoy i kosmicheskoy meditsine, 1963. Aviatcionnaya i kosmicheskaya meditsina (Aviation and space medicine); materialy konferentsii. Moscow, 1963, 232-236

TOPIC TAGS: cosmonaut, weightlessness, parabolic trajectory, motor coordination, excess gravity

ABSTRACT: Experiments were performed in a two-seater airplane and in a flying laboratory permitting periods of weightlessness of 35-45 and 20-25 seconds, respectively. Each flight included 3-6 periods of weightlessness, with 10-15 minute intervals. The cosmonauts were either fastened to the seat, or were allowed to "swim" freely in the cabin, and records were made of the EKG, blood pressure, pulse rate and respiration, muscular strength and motor coordination (writing test, coordinograph studies and free "swimming" movement). Analysis of the data showed that the cosmonauts who were fastened to the seat showed no changes in motor coordination, while those who were free were usually unable to perform the assigned writing task, even though the coordinograph showed no disturbances in movement.  
Card 173

ACCESSION NR: AT4042684

During free "swimming" in the cabin, the cosmonauts could move only with the aid of a cable or around the wall. The accuracy of assigned movements such as turning of the body with the eyes open or closed, however, was not disturbed. During the first period of weightlessness, there was some alertness and tension, but during the following tests the cosmonauts learned to deal with it and carried out their duties more economically and with better coordination. The emotional reactions to weightlessness differed in different cosmonauts, as shown by the palleness of the face in Nikolayev and the marked flush in Popovich. The intake of natural food during weightlessness was not disturbed. The muscular strength (dynamometry) during free "swimming" was decreased by 4-8 kg. The respiratory rate increased by 6-8 cycles/minute during the period of excess gravity in Gagarin and Titov, becoming normal during weightlessness, while in Nikolayev and Popovich it did not change significantly under excess gravity but increased by 3-7 cycles/min. during weightlessness. The heart rate increased by 20-63 beats per minute under excess gravity and decreased by 16-66 beats/minute in most cases during weightlessness. The systolic blood pressure increased by 10-28 mm Hg under excess gravity. In the EKG, as the heart rate increased, the R-R intervals shortened, and the P-Q and Q-T intervals shortened slightly, but during weightlessness a tendency toward normalization appeared. In all cases, these changes were functional and adaptive in character. The subjective reactions of the cosmonauts during weightlessness are also described.

PHYSIOLOGICAL REACTIONS OF ANIMALS IN HIGH-ALTITUDE ROCKET FLIGHTS (USSR)

Kas'yan, I. I. IN: Akademiya nauk SSSR. Izvestiya. Seriya biologicheskaya, no. 2, 1963, 201-213.

S/216/63/000/002/001/004

Six dogs weighing 5-7 kg were sent aloft in ballistic rockets to altitudes of 450 to 473 km for the purpose of studying the effects of acceleration and weightlessness on basic physiological functions of animals. During powered flight the respiration frequency tended to increase by 45 to 75 cycles per min. The high initial rate of respiration of one dog dropped to less than half, only to rise again when the weightless state was reached. The respiration rates of the other dogs, which had increased during powered flight, dropped almost to prelaunch levels when weightlessness was achieved. Pulse frequency increased by 45 to

Card 1/2

## PHYSIOLOGICAL REACTIONS [Cont'd]

S/216/63/000/002/001/004

120 beats per minute during powered flight and tended to subside after weightlessness set in. Systolic pressure rose by as much as 95 to 100 mm Hg during powered flight, but increases in diastolic pressure were negligible in most cases, increasing by 60 mm in only one case. The EKG showed sharp increases in P<sub>2</sub>, R<sub>2</sub>, and T<sub>2</sub> peaks, and a reduction in the RR, QT, and QRS intervals. The systolic index rose from 33% to 54%. The electrical axis of the heart shifted from 40°-55° to 53°-64°. Toward the end of the weightless period, most indicators returned to their initial levels. The changes produced by acceleration and weightlessness were reversible and nonpathological. Four years later the dogs had failed to show any adverse effects of rocket flights.

880-891

TOPIC TAGS: weightlessness, space orientation, spacesickness,  
sensory disturbance, cardiovascular system, respiratory system, tachycardia

ABSTRACT: Data obtained in experiments with animals indicate the following pattern of changes in vegetative indices induced by the state of weightlessness: a tendency toward tachycardia and an increase in the respiration rate in the early stages of weightlessness. These changes were not pathological, which indicates that the organism is highly adaptable to the conditions of weightlessness. Information obtained from the flights of the Soviet cosmonauts proved that the human organism is able to tolerate weightlessness up to five days without suffering ill effects. The work capacity

Card 1/2

ACCESSION NR: AP4000985

of the cosmonauts was not impaired while they were strapped to their seats. However, when they left their seats and were "floating," their activity was limited practically to communicating with ground stations or with each other. All cosmonauts showed the same general pattern of response to the state of weightlessness. Exposure to weightlessness of short duration produced tachycardia and changes in the respiratory system. These functional changes gradually returned to normal under the effect of prolonged weightlessness, but the resistance to overloads was reduced. Means must be found to counteract the harmful effect of weightlessness in long-range flights. This could be done either by developing the resistance of the human organism or by technical improvement of the spaceships. Producing artificial gravity on spaceships may solve the problem.

TITLE: Dynamics of hemocirculatory parameters of the cerebrovascular system during longitudinal gravitational loads

SOURCE: AN SSSR. Izv. Seriya biologicheskaya, no. 2, 1964, 280-297

TOPIC TAGS: cerebral blood circulation, cerebrovascular hemocirculatory system, gravity acceleration, longitudinal gravitational load, blood pressure change, blood volume change, electroplethysmograph, data unit electrical system, cerebrospinal blood pressure change, central nervous system development, respiration movement, brain oxygen intensity, gravitational load sensitivity threshold, cerebrovascular mechanical regulation, cerebrovascular chemical regulation

ABSTRACT: In a series of 64 experiments changes in blood volume and pressure were studied in the cerebrovascular systems of dogs, cats, rabbits, and rats. In each of the experiments the animal was subjected to 15-20 tests on a rotating stand with longitudinal

Card 1/3

ACCESSION NR: AP4026727

gravitational loads up to + 1 g, and in some experiments animals were tested on a centrifuge with acceleration up to 10 g. Blood volume changes were measured by electroplethysmograph and blood pressure changes were recorded by tensioelectric manometers. Arterial pressure and respiratory movement were measured by data units, and oxygen intensity in the brain was determined by a polarographic method. Readings for all data units were registered on a K 12 21 oscillograph. Results show that the sensitivity threshold of the cerebrovascular system to longitudinal gravitational loads lies within limits of 0.2 to 0.5 g, depending on central nervous system development and the ecology of the animal. The active physiological reactions of the cerebrovascular system 5-10 sec after exposure to longitudinal gravitational loads are autoregulatory, with arterial pressure changes affecting vessel tone. With lack of oxygen and CO<sub>2</sub> accumulation in the brain 15-25 sec after exposure, compensatory reactions of a chemical regulatory nature appear. Orig. art. has: 13 figures, 3 tables.

TITLE: Circulation of the blood during weightlessness

SOURCE: AN SSSR. Izv. Sariya biologicheskaya, no. 3, 1964,  
352-368

TOPIC TAGS: weightlessness, hemodynamics, circulation

ABSTRACT: The authors review data collected on weightlessness from the first flights of dogs in high altitude rockets in the 1949-1956 period to the last manned spaceflight of Bykovskiy and Tereshkova. Data collected during these high-altitude and orbital flights include pulse frequency, arterial pressure, and bioelectrical activity of the heart (EKG). An analysis of these data indicates an absence of serious disruptions of circulation of the blood. Weightlessness, whether short-term or up to 5 days in duration, causes three types of reactions. The first is a distinct reduction in pulse frequency, accompanied by a reduction of arterial pressure (sometimes lower

TITLE: Reactions of the vascular system in the intracranial cavity to equivalents of longitudinal g-loads

SOURCE: AN SSSR. Otdeleniye biologicheskikh nauk. Problemy\* kosmicheskoy biologii, v. 3, 1964, 366-378

TOPIC TAGS: acceleration, brain, circulation, cerebral circulation

ABSTRACT: Electropilethysmographic (EPG) methods have been used to study intracranial hemodynamics in response to simulated or equivalent longitudinal g-loads obtained by rotating animals (rats, rabbits, and cats) in a vertical plane. The vectorial gravitational changes so produced induced active reactions in the vascular system of the brain. These changes occur 4 to 8 sec after the body posture has been changed. Their function is to normalize the blood filling of the intracranial cavity. Special experiments have shown that these active reactions are specific for cerebral blood vessels and that their threshold of sensitivity appears when the change is equivalent to 0.3 to 0.4 g. The data obtained indicate that

Card 1/2

ACCESSION NR: AT4037706

when animals are subjected to simulated longitudinal g-loads (head down), the organs of the central nervous system undergo a shortage of circulation and require compensation on the part of adaptive mechanisms.

TITLE: Sensitivity of the vestibular analyzer and sensory reactions  
of man during short-term weightlessness

SOURCE: AN SSSR. Izv. Seriya biologicheskaya, no. 3, 1964, 369-375,

TOPIC TAGS: weightlessness, vestibular analyzer, parabolic flight,  
rotation, Coriolis acceleration, postrotational stability, nystagmus

ABSTRACT: Research on weightlessness has established that all persons may be classified into three groups on the basis of vestibular-sensory reactions. Group I consists of persons who can stand weightlessness without deterioration of general well-being or loss of work capacity. Group II consists of persons who suffer from illusory sensations concerning the orientation of their bodies in space. Group III consists of persons in whom adverse reactions appear rapidly and lead to the onset of motion sickness (nausea, vomiting, etc.), and

Card 1/3

ACCESSION NR: AP4037623

who became temporarily unable to work. A group of thirty subjects from all three categories, who had participated in parabolic flights, were subjected to a series of tests which involved rotation, rocking, Coriolis accelerations, inhibition of vestibular reactions, and post-rotational stability. The stability of the vestibular analyzer was judged on the basis of vegetative disturbances, duration of the post-rotational nystagmus, duration of illusions of counter-rotation, time required to regain balance on a chair with an unstable support, and duration of the "banking" illusion during the test involving inhibition of vestibular reactions. Results of these experiments show that the degree of sensory reactions under conditions of short-term weightlessness depends basically on variations in vestibular sensitivity of persons subjected to this test. Results obtained with ground experiments indicate that the ability of man to retain his work capacity in conditions of short-term weightlessness can be predicted on the basis of ground experiments. Ground tests show that persons in Group I are characterized by a low sensitivity of the vestibular analyzer to adequate stimulation and a sufficiently high level of inhibitory action on the vestibular analyzer by other afferent systems.

Card 2/3

ACCESSION NR: AP4037623

Group II persons manifest spatial illusions, an increased sensitivity of the vestibular analyzer to adequate stimuli, and a fairly pronounced inhibitory effect on the vestibular analyzer by other analyzer systems. Persons from Group III are characterized by high sensitivity of the vestibular apparatus to adequate stimulation and a weak inhibitory effect of other afferent systems on the vestibular apparatus. TITLE: On the physiological mechanisms of the effect of weightlessness on the human body.

SOURCE: AN USSR Investigative Service document, no. 1, 1970.

Weightlessness may cause sensory illusions (vanging upside down, falling, etc.); weightlessness may affect the reception of light signals (appearance of violet aureoles around lighted objects and increased reception of colors, especially yellow); it may disrupt the coordination of movements; it may affect certain vegetative functions (reduction of the frequency of cardiac contractions, reduction of blood pressure, etc.); and it may lead to motion sickness (as it did in the case of the cosmonaut Titov). There can have been several explanations of the mechanism of weightlessness.

TITLE: Reactions of cosmonauts to conditions of weightlessness *2, 44*

SOURCE: AN SSSR. Otdeleniye biologicheskikh nauk. Problemy kosmicheskoy biologii, v. 4, 1965, 270-289

TOPIC TAGS: manned spaceflight, weightlessness, space physiology, biologic respiration, cosmonaut, physiologic parameter, EKG

ABSTRACT: The authors review and consolidate data obtained from the flights of Vostoks 2-6. These data are given in the enclosed graphs and tables. The authors conclude that an important future experimental problem will be to establish the optimum magnitude of artificial gravity which will overcome the deleterious effects of weightlessness during prolonged manned spaceflights. Orig. art. has: 5 figures and 8 tables. [ATD PRESS: 4091-F]
